Quiz Instructions

Question 1 11.5 pts

The detection of most extra-solar planets is done by

- ☐ imaging them with the Hubble Space Telescope and a occulting disk over their star.
- ☐ seeing the drop in light as they transit their star's disk.
- ☐ seeing them in the infrared with the new Spitzer Space Telescope.
- ☐ receiving radio signals from them.
- ☐ noting Doppler shifts due to their gravitational influence on their star's motion.

Question 2 11.5 pts

In 1995 planets were found orbiting a star in the constellation of

- ☐ Perseus
- ☐ Orion
- ☐ Pegasus
- ☐ Andromeda

Question 3 11.5 pts

gravitational lensing can be used to detect planets. It is based on

- ☐ thermodynamics

Newton's law

special relativity

general relativity

Question 4 11.5 pts

So far, beyond the solar system the extrasolar planets found have been mostly

brown dwarfs much more massive than Jupiter.

large jovians with terrestrial-type orbits.

terrestrials very close to their star, and transiting its disk.

large jovians orbiting solar-type stars about where our jovians are found.

terrestrials with very elongated, distant orbits like comets.

Question 5 11.5 pts

When we are lucky enough to see an extra-solar planet transit its star

we can be certain it is a terrestrial, not a jovian.

we can by the drop in light find the planet's size, mass, and density.

we can determine its shape.

we can determine what elements are in its atmosphere.

it will cause the star to vanish for several hours.

Question 6 11.5 pts

surprisingly, most orbits of exoplanets are

circular

linear

☐

simusoidal

☐

eccentric

Question 7 11.5 pts

Exoplanets like hot jupiters can make their star to wobble

☐

False

☐

True

Question 8 11.5 pts

When a star tugged by a planet moves toward us

☐

The star does not move

☐

Whaaaaat

☐

it is blueshifted

☐

it is redshifted

Question 9 11.5 pts

The very first planets detected in 1992 were orbiting

☐

a pulsar

☐

a sun like star

☐

a brown dwarf

☐

a white dwarf
